

INSTALL GUIDE

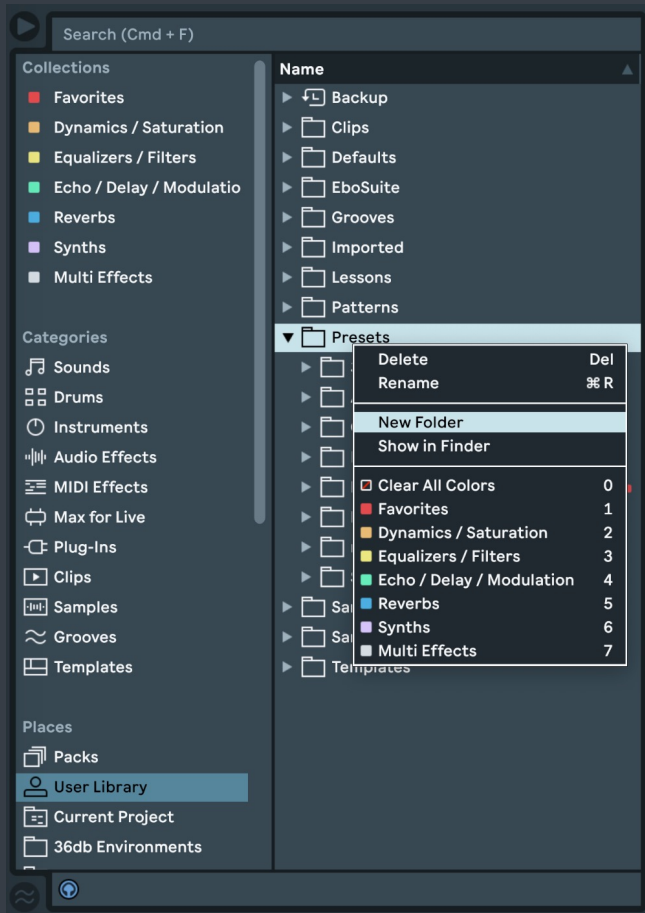

36db

WHEREVER YOUR CREATIVITY TAKES YOU

This guide will show you how to install our 36db Lo-Fi Wobble Box into your User Library in Ableton Live.

Firstly, we need to prepare your User Library for the content. This will ensure a smooth and hassle-free installation.

Once this is done, we'll unpack our 36db Lo-Fi Wobble Box.alp file and add the new product folder to this newly created 36db Environments folder in your User Library.

In Ableton Live, right click on the Presets folder in your User Library and select the New Folder option from the menu. Name the folder '36db Environments'.

This will create the location in your User Library for all your 36db Environments.

Skip this section if you have previously installed one of our products.

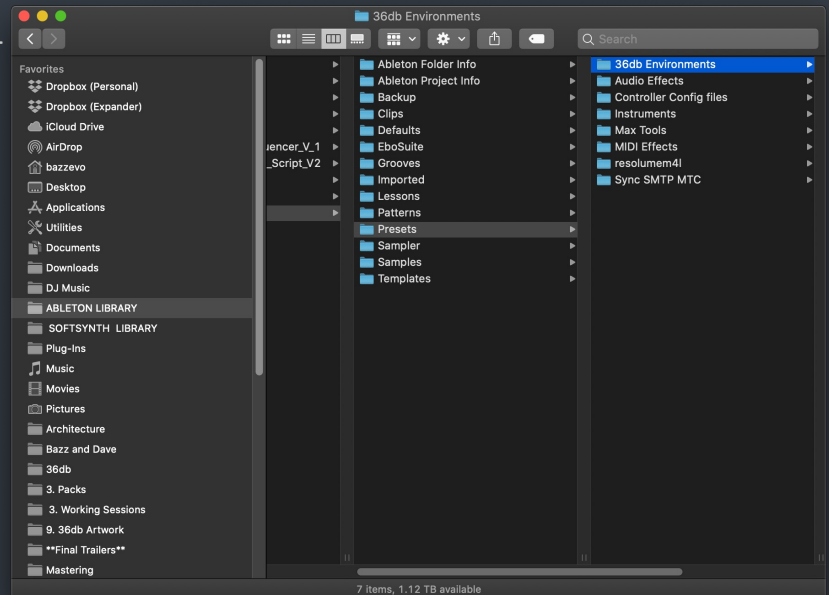

Now it's time to open and install the 36db Elements Pack file. Unzip the file, and you'll find a 36db Lo-Fi Wobble Box folder containing all the contents.

Double Click the .alp pack file. You'll be prompted to unpack the contents and select where to unpack the file. We recommend your desktop.

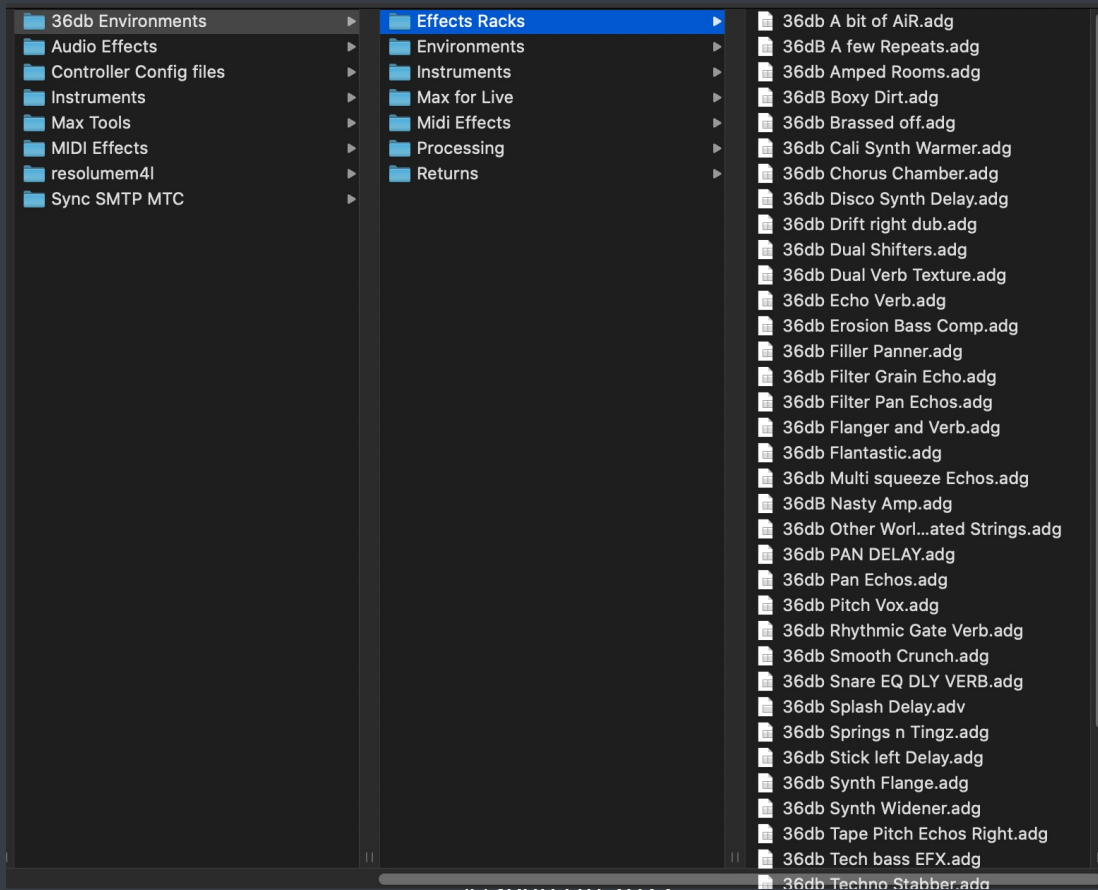

Select the newly created 36db Lo-Fi Wobble Box Project folder you just installed on your Desktop, then copy and move it to your Ableton User Libraries new 36db Environments folder.

Your products should now be visible in your Live browser. You may need to restart Ableton for the browser to update. Then the folders will be visible.

Tip: You can create Individual Presets folders for each type of Instrument Rack™, Effects Rack™, Drum Rack™ or Return Effects Rack™. This is a cool way to keep things organised in your browser. All you need to do is drag & drop the type of Rack from the session in to the relevant folders in the Ableton Browser. This will ensure a smooth installation, and all included files will be copied to your User Library. Create the folder types for your presets in your 36db Environments folder, just as you did earlier. We do recommend Re-scanning your User library after doing this. Go to: File Menu, Manage files then select the third option, Manage User Library. This will then scan your library for missing files. There are helpful tips on fixing any issues within your user library Ableton help.

You're all set. You should now have a 36db Environment Project folder in your User Library. Enjoy!

Troubleshooting

Once your files are unzipped, if you find your Mac/PC does not recognise the file format, this is because the OS removed the .alp extension from the file name after it was unzipped. Simply add the .alp extension to the name, then your OS should recognise the file type as an Ableton file.

If you don't see your 36db Environments folder in your Ableton browser, simply restart Live. The browser will then re-index your browser content. This can take some time if you have a large library, but it will fix the issue.

If you have any issues with files being damaged or corrupted after installation, try re-downloading the content again, and go through the same process of installation.

If this still doesn't work for you, contact support@36db.live and we will do our utmost to rectify your issues.
